

Sentence Segmentation Under Adversarial Punctuation In Scholarly Documents

Prior work (Smith et al., 2020) reported an effect at $p < 0.05$ across three cohorts. We replicated this in a pre-registered sample. See Fig. 3 for the full distribution, and cf. Jones for a contrasting account of the international variation observed in these data.

Participants ($N = 24$, mean age 22.4 yrs) completed 3 runs of the task. Each run took 6.5 min. The dataset is open access. We used a Butterworth filter, i.e. a maximally flat response, before resampling to 1 kHz. The pipeline was implemented by J. R. Smith and validated against the U.S. National Institute of Standards reference set. Stimuli included images, sounds, etc. Results were consistent across modalities. Although the effect was small in the first cohort, we

observed a consistent increase across all three replication samples, which suggests that the underlying mechanism is robust.

Analyses were carried out in a standard environment. No participant was excluded after the pre-registration was filed. Confidence intervals are reported throughout, and all code is available on request.
